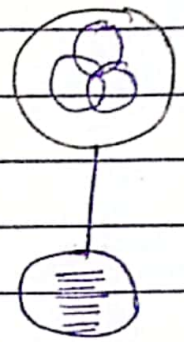
Microservices

Monolithic Architecture

with been combined single code base or repository every thing

- High CI/CD pipeline are there
- for personal project, startup (small) Follow monolithic Architecture.



Adv:

(i) Easier to develop
(ii) Easier to navigate

Disadv:

(1) Redeployment (by changing)
(2) Scaling limitation
(3) Lots of dependency

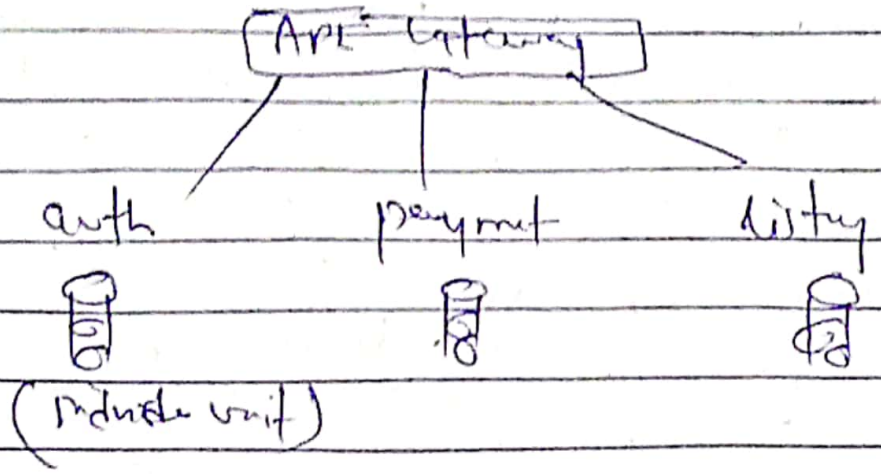
ie: Netflix, Uber, amazon

microservices Architecture:

UI

In this we break the individual Application in individual services that work on own individual unit

Microservice Archi



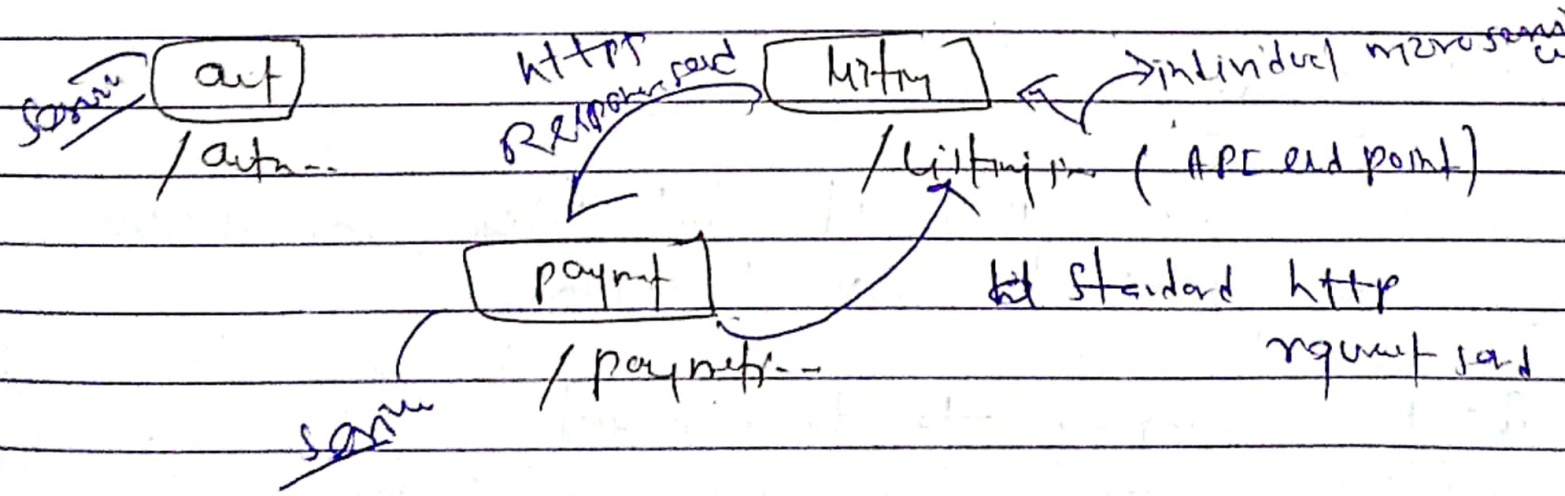
→ How this work

1. Independent Development
2. separate codebase
3. separate repositories
4. Independent deployment

Adv & Benefits:

- Independent Development
- Flexible Scalability
- Technology Flexibility (coding in different language)

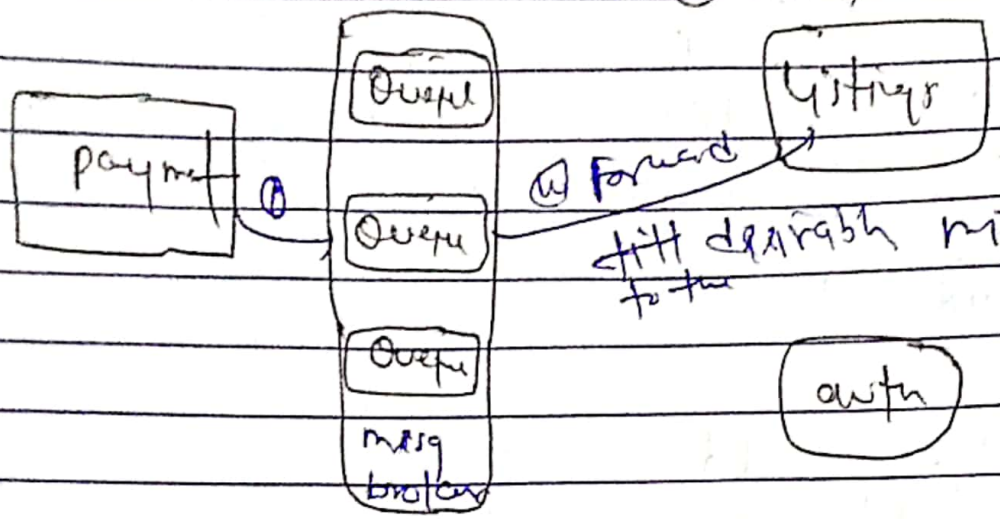
synchronous communication:



Asynchronous communication :

Date
Page No.

→ Message Broker (① RabbitMQ
② Apache Kafka)



③ 3rd type communication is done with :

① Istio (Servicemesh)

→ it is used on microservices in deployment on Kubernetes.

Disadv :

But its not like microservices is perfect Architecture

① → complex to development
(ii) management overhead / (Team)
(iii) High Infra costs (personal, CI/CD, containers)
